

- ⑥3 [Jkⁿ # (7.14), part (a) only]. For a frequency-dependent dielectric constant $\epsilon(\omega)$, with: $\text{Im } \epsilon(\omega) = \lambda [\theta(\omega - \omega_1) - \theta(\omega - \omega_2)]$, $\omega \lambda = \text{const}$, $\theta = \text{unit step fcn}$, and ordering $\omega_2 > \omega_1 > 0$, use the Kramers-Kronig relations to find $\text{Re } \epsilon(\omega)$ at all $\omega > 0$. Sketch both $\text{Im } \epsilon(\omega)$ & $\text{Re } \epsilon(\omega)$ vs. ω . Compare your results for this model of $\epsilon(\omega)$ with the generic curves in Jkⁿ Fig. 7.8.

- ⑥4 [Jkⁿ # (11.2)]. Show explicitly that two successive Lorentz Transformations in the same direction (at velocity β_1 , followed by β_2) are equivalent to a single LT @: $\beta = (\beta_1 + \beta_2) / (1 + \beta_1 \beta_2)$, $\omega \beta = v/c$. This is relativistic velocity addition.

- ⑥5 Initially, K' is moving at velocity $\beta_1 = \beta$ ($\omega 0 < \beta < 1$) down the x -axis of reference system K . To boost her velocity, K' boards a system K'' moving by her at relative velocity β . By velocity addition, K' is now moving w.r.t. K @ $\beta_2 = 2\beta / (1 + \beta^2)$. K' continues the process, each time boarding a new system $K^{(m)}$ moving by her at β . Show that after $(n-1)$ such boosts, the K' velocity relative to K is: $\beta_n = (1 - \epsilon^n) / (1 + \epsilon^n)$, $\omega 0 < \epsilon < 1$. Find ϵ in terms of β . Can K' get to $v=c$ by a finite number of finite accelerations?

- ⑥6 Newton's $F = m\ddot{x}$ can be replaced in SRT by $\tilde{F} = m\tilde{a}$. The Minkowski 4-force \tilde{F} is defined in terms of m 's 4-momentum $\tilde{p} = (E/c, \mathbf{p})$ [$\omega E = \gamma mc^2$, $\mathbf{p} = \gamma m\mathbf{u}$, and $\gamma = 1/\sqrt{1 - u^2/c^2}$] by: $\tilde{F} = d\tilde{p}/d\tau$, $d\tau = \frac{1}{\gamma} dt = \text{particle proper time}$ (and dt is observer's time in a reference frame K). The 4-acceleration \tilde{a} is defined by the 4-velocity $\tilde{u} = \gamma(c, \mathbf{u})$ as: $\tilde{a} = d\tilde{u}/d\tau$.

(A) Show that $\tilde{F} \cdot \tilde{u} \equiv 0$, for the motion of m .

(B) From part (A), establish the relativistic work-energy theorem: $\underline{F \cdot u = dE/dt}$, $\omega E = \gamma mc^2 = E(u)$. $\mathbf{F} = d\mathbf{p}/dt$ ($\omega \mathbf{p} = \gamma m\mathbf{u}$) is the Newtonian force observed by K .

63) [Jkⁿ # (7.14)(a)]. $\text{Im} \epsilon(\omega) = \lambda [\theta(\omega - \omega_1) - \theta(\omega - \omega_2)] \Rightarrow \text{Re} \epsilon(\omega) = ?$

1. From Jkⁿ Eq. (7.120), the prescription for $\text{Re} \epsilon(\omega)$ is...

$$\rightarrow \frac{\pi}{2} [\text{Re} \epsilon(\omega) - 1] = \mathcal{P} \int_0^{\infty} \frac{x \text{Im} \epsilon(x)}{x^2 - \omega^2} dx = \lambda \mathcal{P} \int_0^{\infty} \frac{x [\theta(x - \omega_1) - \theta(x - \omega_2)]}{x^2 - \omega^2} dx,$$

$$\text{or } \frac{\pi}{2\lambda} [\text{Re} \epsilon(\omega) - 1] = \mathcal{P} \int_{\omega_1}^{\omega_2} \frac{x dx}{x^2 - \omega^2} = \frac{1}{2} \mathcal{P} \int_{\omega_1^2}^{\omega_2^2} \frac{dy}{y - \omega^2}, \quad y = x^2. \quad (1)$$

2. Suppose the running frequency $\omega \neq \omega_1$ or ω_2 . Then Eq. (1) gives...

$$\rightarrow \frac{\pi}{\lambda} [\text{Re} \epsilon(\omega) - 1] = \int_{\omega_1^2}^{\omega_2^2} d \ln(y - \omega^2) = \ln \left| \frac{\omega_2^2 - \omega^2}{\omega_1^2 - \omega^2} \right| \quad (2)$$

$$\left\{ \begin{array}{l} 0 \leq \omega < \omega_1 : \text{Re} \epsilon(\omega) = 1 + \frac{\lambda}{\pi} \ln \left(\frac{\omega_2^2 - \omega^2}{\omega_1^2 - \omega^2} \right), \quad (3a) \end{array} \right.$$

$$\left\{ \begin{array}{l} \omega_1 < \omega < \omega_2 : \text{Re} \epsilon(\omega) = 1 + \frac{\lambda}{\pi} \ln \left(\frac{\omega_2^2 - \omega^2}{\omega^2 - \omega_1^2} \right), \quad (3b) \star \end{array} \right.$$

$$\left\{ \begin{array}{l} \omega_2 < \omega : \text{Re} \epsilon(\omega) = 1 + \frac{\lambda}{\pi} \ln \left(\frac{\omega^2 - \omega_2^2}{\omega^2 - \omega_1^2} \right). \quad (3c) \end{array} \right.$$

Note that in region (2), the $\ln \rightarrow 0$ @ $\omega_0 = \sqrt{(\omega_1^2 + \omega_2^2)/2}$, and in region (3) $\text{Re} \epsilon(\omega) \rightarrow 1$ as $\omega \rightarrow \infty$ (standard behavior).

3. At the boundary freqs. $\omega_1 \neq \omega_2$...

$$\left. \begin{array}{l} \text{region (1)} \\ \omega = \omega_1 - \delta \end{array} \right\} \text{Re} \epsilon(\omega) \approx 1 + \frac{\lambda}{\pi} \ln \left(\frac{\omega_2^2 - \omega_1^2}{2\omega_1 \delta - \delta^2} \right) \rightarrow +\infty, \text{ as } \delta \rightarrow 0$$

$$\left. \begin{array}{l} \text{region (2)} \\ \omega = \omega_1 + \delta \end{array} \right\} \text{Re} \epsilon(\omega) \approx 1 + \frac{\lambda}{\pi} \ln \left(\frac{\omega_2^2 - \omega_1^2}{2\omega_1 \delta + \delta^2} \right) \rightarrow +\infty, \text{ as } \delta \rightarrow 0$$

$\text{Re} \epsilon(\omega)$ diverges $\sim \ln \frac{1}{|\delta|}$
 $\rightarrow \infty$ when approaching ω_1 from above or below.

Similarly, as $\omega \rightarrow \omega_2 \pm$, $\text{Re} \epsilon(\omega) \approx 1 + \frac{\lambda}{\pi} \ln \left(\frac{2\omega_2 \delta}{\omega_2^2 - \omega_1^2} \right) \rightarrow (-)\infty$. There is no apparent way to remove these divergences [due to ∞ derivatives $(d/d\omega) \text{Im} \epsilon(\omega)$ @ $\omega = \omega_1$ & ω_2 , normally forbidden in a theory of analytic fns]. So they must stay in above sketch. (4)

4. $\text{Im} \epsilon(\omega) \neq \text{Re} \epsilon(\omega)$ above resemble Jkⁿ Fig. 7.8. But the $\omega_{1,2}$ problems \Rightarrow this model is poor.

★ For $\omega_1 < \omega < \omega_2$, Eq. (3b) is defined by the \mathcal{P} , i.e. $\int_{\omega_1^2}^{\omega_2^2} \frac{dy}{y - \omega^2} = \lim_{\delta \rightarrow 0} \left\{ \int_{\omega_1^2}^{(\omega - \delta)^2} + \int_{(\omega + \delta)^2}^{\omega_2^2} \right\} \frac{dy}{y - \omega^2} =$
 $= \lim_{\delta \rightarrow 0} \left\{ \ln \left(\frac{\omega_2^2 - \omega^2}{\omega^2 - \omega_1^2} \right) + \ln \left(\frac{\omega^2 - (\omega + \delta)^2}{(\omega + \delta)^2 - \omega^2} \right) \right\} = \ln \left[(\omega_2^2 - \omega^2) / (\omega^2 - \omega_1^2) \right]$, as stated.

$$\begin{array}{c} K \\ \downarrow \\ \beta_1 \\ \downarrow \\ x'_1 \\ x_1 \end{array} + \begin{array}{c} K' \\ \downarrow \\ \beta_2 \\ \downarrow \\ x''_1 \\ x'_1 \end{array} = ? \quad \text{S84}$$

⑥ Find equivalent velocity for two successive Lorentz transfⁿs [Jkⁿ#(11.2)].

1) Two successive Lorentz transfⁿs (along x_1 -axis) yield, with $x_0 = ct \dots$

$$\underline{K \rightarrow K'(\beta_1)} \begin{cases} x'_0 = \gamma_1(x_0 - \beta_1 x_1), \\ x'_1 = \gamma_1(x_1 - \beta_1 x_0); \end{cases} \parallel \underline{K' \rightarrow K''(\beta_2)} \begin{cases} x''_0 = \gamma_2(x'_0 - \beta_2 x'_1), \\ x''_1 = \gamma_2(x'_1 - \beta_2 x'_0). \end{cases} \quad (1)$$

2) Plug the x'_0 & x'_1 values from the $K \rightarrow K'$ transform into the x''_0 & x''_1 eqns to get

$$\begin{aligned} x''_0 &= (1 + \beta_1 \beta_2) \gamma_1 \gamma_2 \left[x_0 - \left(\frac{\beta_1 + \beta_2}{1 + \beta_1 \beta_2} \right) x_1 \right], \\ x''_1 &= (1 + \beta_1 \beta_2) \gamma_1 \gamma_2 \left[x_1 - \left(\frac{\beta_1 + \beta_2}{1 + \beta_1 \beta_2} \right) x_0 \right]. \end{aligned} \quad (2)$$

3) Now work out the algebraic identity...

$$\begin{aligned} (1 + \beta_1 \beta_2) \gamma_1 \gamma_2 &= \left[\frac{(1 + \beta_1 \beta_2)^2}{(1 - \beta_1^2)(1 - \beta_2^2)} \right]^{\frac{1}{2}} = \left[\frac{(1 + \beta_1 \beta_2)^2}{(1 + \beta_1 \beta_2)^2 - (\beta_1 + \beta_2)^2} \right]^{\frac{1}{2}} = \left[\frac{1}{1 - \left(\frac{\beta_1 + \beta_2}{1 + \beta_1 \beta_2} \right)^2} \right]^{\frac{1}{2}} \\ &= 1 + (\beta_1 \beta_2)^2 - (\beta_1^2 + \beta_2^2) = 1 + 2\beta_1 \beta_2 + (\beta_1 \beta_2)^2 - (\beta_1^2 + 2\beta_1 \beta_2 + \beta_2^2), \end{aligned}$$

i.e. $(1 + \beta_1 \beta_2) \gamma_1 \gamma_2 = \gamma$, where: $\gamma = \frac{1}{\sqrt{1 - \beta^2}}$, and: $\beta = (\beta_1 + \beta_2) / (1 + \beta_1 \beta_2)$. (3)

4) The overall $K \rightarrow K''$ transfⁿ of Eq. (2) can now be written as...

$$x''_0 = \gamma(x_0 - \beta x_1), \quad x''_1 = \gamma(x_1 - \beta x_0),$$

with: $\boxed{\beta = (\beta_1 + \beta_2) / (1 + \beta_1 \beta_2)}$, and: $\gamma = 1 / \sqrt{1 - \beta^2}$. (4)

This is a standard Lorentz transfⁿ for $K \rightarrow K''(\beta)$, at the advertised value of β . Velocities do not add linearly, as per Galileo. While K' thinks he boosts his velocity by β_2 in boarding K'' , he only gets: $\beta - \beta_1 = \left(\frac{1 - \beta_1^2}{1 + \beta_1 \beta_2} \right) \beta_2 < \beta_2$, w.r.t. K .

⑥ Calculate aggregate velocity for a succession of Lorentz transf^s at β .

1) After $(n-1)$ boardings, the $K-K'$ relative velocity will be...

$$\beta_n = \frac{\beta + \beta_{n-1}}{1 + \beta\beta_{n-1}} ; \quad n \geq 1, \text{ and: } \beta_0 = 0, \beta_1 = \beta, \beta_2 = \frac{2\beta}{1+\beta^2}; \text{ etc} \quad (1)$$

In principle, this can be iterated for β_n in terms of $\beta_1 = \beta$. The first few terms are...

$$\beta_1 = \beta, \beta_2 = \frac{2\beta}{1+\beta^2}, \beta_3 = \frac{3\beta + \beta^3}{1+3\beta^2}, \beta_4 = \frac{4\beta + 4\beta^3}{1+6\beta^2 + \beta^4}, \quad (2)$$

$$\beta_5 = \frac{5\beta + 10\beta^3 + \beta^5}{1+10\beta^2 + 5\beta^4}, \beta_6 = \frac{6\beta + 20\beta^3 + 6\beta^5}{1+15\beta^2 + 15\beta^4 + \beta^6}, \beta_7 = \frac{7\beta + 35\beta^3 + 21\beta^5 + \beta^7}{1+21\beta^2 + 35\beta^4 + 7\beta^6}, \text{ etc.}$$

2) Consulting a table of binomial coefficients, it is apparent these results follow from:

$$\beta_n = \frac{\sum_{k=0}^{[n/2]} \binom{n}{2k+1} \beta^{2k+1}}{\sum_{k=0}^{[n/2]} \binom{n}{2k} \beta^{2k}} \quad \left\{ \begin{array}{l} [n/2] = \text{greatest integer in } n/2, \\ \binom{n}{m} = n! / m! (n-m)! \end{array} \right. \quad (3)$$

Indeed, this Ansatz satisfies the recursion relation in Eq. (1). Next, note that:

$$\begin{aligned} (1+\beta)^n &= \sum_{m=0}^n \binom{n}{m} \beta^m = \binom{n}{0} \beta^0 + \binom{n}{1} \beta^1 + \binom{n}{2} \beta^2 + \binom{n}{3} \beta^3 + \dots + \binom{n}{n} \beta^n \\ &= \mathcal{A} + \mathcal{N}, \text{ where: } \mathcal{A} = \sum_{k=0}^{[n/2]} \binom{n}{2k} \beta^{2k}, \text{ and } \mathcal{N} = \sum_{k=0}^{[n/2]} \binom{n}{2k+1} \beta^{2k+1}. \end{aligned} \quad (4)$$

Similarly...

$$(1-\beta)^n = \mathcal{A} - \mathcal{N} \quad \text{so} \quad \left\{ \begin{array}{l} \mathcal{A} = \frac{1}{2} [(1+\beta)^n + (1-\beta)^n], \\ \mathcal{N} = \frac{1}{2} [(1+\beta)^n - (1-\beta)^n]. \end{array} \right. \quad (5)$$

3) With these identities, we can form the aggregate velocity of Eq. (3)...

$$\rightarrow \beta_n = \mathcal{N}/\mathcal{A} = (1 - \epsilon^n)/(1 + \epsilon^n), \text{ with: } \boxed{\epsilon = (1-\beta)/(1+\beta)}. \quad (6)$$

With $0 < \beta < 1 \Rightarrow 0 < \epsilon < 1, \dots$ so $\dots 0 < \beta_n < 1$ for any finite # of accelerations. For $n \rightarrow \text{large}$: $\beta_n \simeq 1 - 2\epsilon^n$; we can at most approach $v=c$ from below; $v \leq c$ always.

Ⓔ With Minkowski force: $\tilde{F} = d\tilde{p}/d\tau$, show Work-Energy Thm: $\tilde{F} \cdot \tilde{u} = \frac{d}{dt}(\gamma mc^2)$.

A. 1) The Minkowski version of $F = ma$ is -- as stated...

$$\rightarrow \tilde{F} = \frac{d\tilde{p}}{d\tau} = m \tilde{a}. \quad (1)$$

Since $\tilde{a} = d\tilde{u}/d\tau$, we can form the scalar product of interest...

$$\rightarrow \tilde{F} \cdot \tilde{u} = m \left(\frac{d\tilde{u}}{d\tau} \right) \cdot \tilde{u} = \frac{m}{2} \frac{d}{d\tau} (\tilde{u} \cdot \tilde{u}) = \frac{m}{2} \frac{d}{d\tau} (c^2) = \underline{\underline{0}}. \quad (2)$$

This works because \tilde{u} has the invariant length: $\tilde{u}^2 = c^2 = \text{const}$. So $\tilde{F} \perp \tilde{u}$.

B. 2) In $\tilde{F} = d\tilde{p}/d\tau$, put $\tilde{p} = (\mathcal{E}/c, \mathbf{p})$ [$\mathcal{E} = \gamma mc^2$, $\mathbf{p} = \gamma m \mathbf{u}$, $\gamma = 1/\sqrt{1-u^2/c^2}$], and introduce observer K time dt by $d\tau = (1/\gamma) dt$. Then...

$$\rightarrow \tilde{F} = \gamma \frac{d}{dt} (\mathcal{E}/c, \mathbf{p}) = \gamma \left(\frac{1}{c} \frac{d\mathcal{E}}{dt}, \mathbf{F} \right), \quad (3)$$

$\mathbf{F} = d\mathbf{p}/dt$ the (relativized) version of the Newton 3-force on m seen by K.

The 4-velocity of m is, explicitly...

$$\rightarrow \tilde{u} = \gamma(c, \mathbf{u}), \quad \mathbf{u} = 3\text{-velocity seen by K, and } \gamma = 1/\sqrt{1-u^2/c^2}, \quad (4)$$

... and the 4-vector scalar product in Eq. (2) is ...

$$\rightarrow \tilde{F} \cdot \tilde{u} = \gamma \left(\frac{1}{c} \frac{d\mathcal{E}}{dt}, \mathbf{F} \right) \cdot \gamma(c, \mathbf{u}) = \gamma^2 \left[\frac{d\mathcal{E}}{dt} - \mathbf{F} \cdot \mathbf{u} \right]. \quad (5)$$

But, by Eq. (2), $\tilde{F} \cdot \tilde{u} = 0$, and so the $[] \equiv 0$ here. Thus...

$$\boxed{\mathbf{F} \cdot \mathbf{u} = \frac{d\mathcal{E}}{dt}} \quad \text{with } \mathbf{F} = \frac{d}{dt}(\gamma m \mathbf{u}), \quad \mathcal{E} = \gamma mc^2 \quad \text{as observed in K.} \quad (6)$$

This is the relativistic version of the work-energy theorem. The total energy \mathcal{E} can be replaced by the relativistic kinetic energy $K = (\gamma - 1)mc^2$.
