SRT Introde Link: Causality +> c, as limit.

5) We have just claimed that "carusality" is linked with C as a limiting signal velocity. The following example shows why. Consider events #1 & #2 that occur in reference frame K at times ty & tz. The events are observed also by passing frames K' (to right @ v) & K" (to left @ v). The observed times between events are...

$$\begin{cases} \text{for } K : (t_2 - t_1') = \Delta t; \\ \text{for } K' : (t_2' - t_1') = \Delta t' = \gamma \left[\Delta t - \frac{\Delta t}{c^2} (x_2 - x_1) \right]; \\ \text{for } K'' : (t_2'' - t_1'') = \Delta t'' = \gamma \left[\Delta t + \frac{\Delta t}{c^2} (x_2 - x_1) \right]. \end{cases}$$

$$\begin{cases} \gamma = \frac{1}{1 - v^2/c^2} \\ \text{for both } K' \\ \text{and } K'' \end{cases}$$

Suppose the events are simultaneous for K, i.e. Dt=0. Other observers see:

$$\rightarrow \Delta t = 0 \text{ in } K \Rightarrow \begin{cases} \Delta t' = (-) \frac{\chi v}{c^2} \Delta x < 0, \text{ in } K' \int \text{ event $\# 2$ occurred} \\ \Delta t'' = (+) \frac{\chi v}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x > 0, \text{ in } K'' \int \text{ event $\# 2$ occurred} \\ \frac{\Delta t''}{c^2} \Delta x$$

Here $\Delta x = x_z - x_z$ is the spatial separation between the event locations in K. Note that meither K'nor K" agree on simultaneity in K, and -- because their motions & are oppositely directed -- they don't even agree on the <u>sequence</u> of the events.

Now, suppose K claims event #1 caused #2. This makes sense to K", since he sees #2 after #1. But in K', we see #2 before #1, and the time-ordering for cause > effect is violated. Clearly, to preserve causality for all three observers [i.e. that they all agree event #1 (cause) precedes event #2 (effect)], we must look more carefully at the sequencing #1 => #2.

(next page)

If K claims # 1 causes # 2, he must send a signal -- at some velocity U-- from position x, to x in order to preserve the cause-effect time ordering, 50...

$$S_{2}$$
 $\Delta t = t_{2}(effect) - t_{1}(cause) = \frac{x_{2} - x_{1}}{u} > 0$, in K $\int_{0}^{u} R(cause + effect)$.

Ulsignal) is so far unknown. In K", Dt">0 (per Eg.(23)), so cause → effect is preserved. Now, with Dt>0, K' sees a new temporal ordering...

$$\left[\begin{array}{c} \Delta t' = \gamma \left[\Delta t - \frac{v}{c^2} \Delta x\right] = \gamma \left(\frac{c}{u} - \frac{v}{c}\right) \frac{\Delta x}{c}, \\ \text{Sof Cause} \rightarrow \text{effect ordering} \\ \text{restored in } K' if \Delta t' > 0 \end{array}\right] = \gamma \left(\frac{c}{u} - \frac{v}{c}\right) > 0.$$
 (26)

The signal velocity u (in K) must satisfy this inequality in order that both $K' \notin K''$ agree on the cause \rightarrow effect time-ordering. But $\frac{1}{\sqrt{c}} < 1$ for all physical observers, and so: $\frac{c}{u} > \frac{v}{c}$, for all $\frac{v}{c} < 1 \Rightarrow \frac{c}{u} > 1$. Thus we claim...

To preserve causality in all inertial frames (in relative motion @ U < C), no information-carrying signal can be transmitted at speed u > C. Moreover, C= limit speed for all signals that can causally link events. (27)

While the observer time dt changes with the relative motion, the proper time dt is a Loventz invariant -- it cannot change size when viewed from any inertial frame. It is also the <u>least</u> time, since: $t_2-t_1=\int dt=\int d\tau/\sqrt{1-\beta^2(\tau)} > (\tau_2-\tau_1)$.

An upcoming problem... no physical frame can be accelerated to U=C.
